

Rendering | Render Farm

Render Optimization & Using the BK Renderfarm

Design Informatics

AR0771 – Week 6

Rendering (in CG)

The process of constructing a raster image from a 3D computer model

A description of a scene...

geometry, visual properties of objects, lighting, atmospheric environment and simulation of a camera

... is processed to produce a picture

Rendering (in CG)

Direct and indirect illumination

Rendering involves a huge amount of calculations

Light from other points?

Light from everywhere? (!)

So optimization is key!

Rendering Process Overview

Simplified overview of phases in a typical render process:

- 1. Scene pre-processing Tessellate geometry (NURBs, displacement) Build BSP tree to optimize ray-tracing
- 2. Calculate light distribution Ray-trace Light map, Photon map and Final Gather points
- 3. Render into Framebuffer Combine light data, ray-tracing and shader properties into color values (samples)
- 4. Save image from Framebuffer Anti-aliasing, Color corrections, Lens shaders

Example of a 2D BSP tree

Notes on Pre-processing

NURBS geometry and displacement maps need to be "tessellated" before rendering. This is done on-the-fly each time you render.

- You determine the quality; default may be very poor
- Use the Approximation editor to change settings
- Verify the quality in a full resolution render

<u>A</u>		mental ray Approxim	nation Editor		- 🗆 🗙

Window > Rendering Editors > mental ray > Approximation Editor

LTR: NURBS object, low-quality tessellation, medium

Notes on Final Gathering

Final Gathering is a technique used for indirect lighting (also see the Light lecture)

- The 'right' settings vary heavily from scene to scene
- Simply cranking up all settings to the max will quickly grind your render to a near halt.
- Time spent on iteratively optimizing settings is time well spent: There's much to gain!
- Top 3 Final Gathering Settings: Secondary Diffuse Bounces Accuracy Point Density

Final Gathering (without secondary diffuse bounces)

Notes on Anti-Aliasing

Anti-Aliasing is the process of smoothing edges in a raster image

• It's an easy thing to get right, just don't forget it

Notes on Anti-Aliasing

Control the 'crispness' of the image by choosing the Sampling Filter that is used

Color Management

- There's an issue with (linear) color values used in CG and how we perceive color
- Not getting it right leads to incorrect, awful colors

Correct color management

Original textures

Incorrect color management (washed out)

You have to change the defaults to get it right!

Color Management

Some background on this issue: Color values and representation

- Our eyes' sensitivity to light is non-linear
- Most computer image formats use this fact to translate linear color values into gamma corrected values

This yields more precise colors for values we are more sensitive to. This means smaller image size, or more perceived precision within the same file size

Color Management

The problem:

- Maya expects textures to be in 'linear' color space
- Most file textures (images) are not. They are in sRGB space (gamma 2.2)

sRGB (gamma 2.2)

linear (gamma 1.0)

Because working with linear texture images is not practical we need to fix it through proper Color Management

Color Management and Lights

- The output of the rendering process can be in any color space: linear, sRGB or other.
- Without color management, renders are usually stored in sRGB: gamma 2.2.
- To get proper lighting behavior, it's recommended to render to linear output;

The decay Rate of lights should be set to Quadratic

Color Managed Output

When rendering to linear color space, the result will look too dark:

Uncorrected display in Render View (linear)

Corrected display in Render View (linear->sRGB)

Color Management - Maya

Enabling Color Management in Maya (<2016)

A	Render Settings – 🗆 🗙	A	Render View

Color Management - Maya

When using mia_exposure_simple (or mia_exposure_photographic), for instance when you enable Physical Sun and Sky:

Set the mia_exposure gamma to 1.0 instead of 2.2 (default)!

Color Management - Photoshop

When you open a linear image in Photoshop, you need to apply gamma correction (2.2) manually.

Using an Adjustment Layer is the preferred method

Optimizing your Render Process

Recap:

- Modeling vs Textures (covered in modeling and textures lectures)
- Shaders: reflections, glossiness (covered in materials lecture)

New:

- Render View: Test resolution, Region rendering
- Clean your scene: history, unused geometry, curves
- Textures: appropriate resolution
- Render Settings: tweaking, presets for tests and production

Optimization: Render View

Region Rendering and snapshots

Optimization: Render View

Test Resolution

Optimization: Scene

- Remove geometry that is no longer needed
- Delete unused layers and render layers
- Delete history

	Optimize Scene Size Options 🛛 🗕 🔍

Optional: File > Optimize Scene Size

Hypershade: delete Unused Nodes

Always make a backup of your Scene first!

Optimization: textures

Resolution

- Don't create large textures just because you can
- Relate the size to the size of the texture in the final image

Final poster A1 841 x 594 mm	@100 pixels per inch: 3310 x 2340 pixels@120 pixels per inch: 3972 x 2808 pixels@150 pixels per inch: 4965 x 3510 pixel
33.1 x 23.4 inch Texture	Example: the texture is roughly 1/4 th of the image. If the image is 3310 pixels wide, the texture would roughly take up 830 pixels in width.
	Double this value and round up for some margin and 2048x2048 should be sufficient for your texture.

Each 4096 x 4096 pixel texture takes up 64MB of memory during rendering

Project and Texture Problems

If *at any point in time* you've opened your scene without setting your Project properly, your scene will contain texture location errors

Use the Texture Tools from the TOI shelf in Maya to remedy this

TOI Texture Tools

- Make sure you've Set your Project in Maya
- Conform texture locations to project': Fix problems with texture locations in your entire scene
- Test:

Perform a dry-run of above. Outputs in log, but doesn't actually do anything yet

• Conform textures and delete orphaned:

... and also delete file nodes from hypershade that are no longer used

Optimization: Render Settings

Most important for quality and speed:

- Sampling (Anti Aliasing)
- Ray Tracing
- Final Gathering | Global Illumination

Sampling

To get good anti-aliasing quality, you need multiple samples per pixel

Dots are pixel centers, but not sample locations.

Sampling

• Samples for Unified Sampling

- Test render: 0.25 0.8
- Final Render: 0.8 2.0

Raytracing settings are split into:

- Reflections
- Refractions
- Shadows

Raytracing is also commonly used to determine what the camera is looking at (primary ray), for ambient occlusion and more

Reflections:

Maximum number of times a ray will reflect when calculating

0 reflections

1 reflections

2 reflections

Motion Steps 1
Motion Blur Optimization
> Shadows
Framebuffer
Legacy Options
Close

Refractions:

Maximum number of times a ray will refract when calculating refractions

Refractions occur when a ray goes through a (semi-) transparent surface.

Max Trace Depth

Maximum allowed reflections + refractions for a single ray

It's just an additional setting to allow for more fine-tuned optimization

You can simply use:

mtr = reflection + refraction

Or choose a value less than the exact sum

Shadows

- Maximum number of times a ray will reflect when calculating shadows
- This setting determines whether a shadow appears in a reflection (of a reflection of a ...)

Shadows 1

Shadows 2

Guidelines:

- Reflections/refractions: 4 10
- Max Trace Depth 50 75% of sum (2 6)
- Shadows: 2 4

Disclaimer: these are very general guidelines. If your scene contains a lot of glass or reflective materials, more refractions reflections or shadow depth *may* be necessary

Accuracy:

The number of rays cast per FG point

- Determines quality in the most direct way
- Subtle light effects demand a high accuracy

Accuracy: number of these guys per FG point

Accuracy:

- Start with 20
- Increase when image is full of spots
- Use steps of 10

Range for production:

Simple lighting: can be as low as 50 Complex lighting, high quality: 1000+

Example of result of low Accuracy, full of 'FG spottiness'

Point Density:

How many places and where Mental Ray will do a full FG calculation in the final image

- Determines overall quality
- 1.0 (100%) means everywhere where MR would initial plan to do a FG calculation
- 0.5 means at 50%, so roughly twice as coarse

FG point visualized. MR intelligently determines where the density needs to - be higher

Image courtesy of Digital Tutors

Point Density:

Start with 0.6 for test renderings

Use 0.8 for test rendering when results are very poor with low Accuracy

- Set to around 1.0 for final renderings
- > 1.2 should normally not be needed

Point Interpolation:

Mental Ray can interpolate values from different FG points This sets how many values to average/weigh.

- Higher values create a smoother image
- Results are less accurate: light gets 'smeared out'
- It's faster than increasing the accuracy

Point camera's looking at and is currently considered

Point Interpolation:

- Set to about half of the Accuracy
- Increase to 1x or 2x the Accuracy as desired (if more accurate results aren't required)
- Keep in sync with Accuracy

Secondary Diffuse Bounces:

Indirect light can 'bounce' even further than the default one indirect bounce, using Secondary Diffuse Bounces.

- Expensive calculation (exponential!)
- Make test renderings to see whether is actually contributes enough to be noticeable

Secondary Diffuse Bounce

Notice the exponentiality

Secondary Diffuse Bounces:

- Leave at 0 if you can
- Increase in steps of one
- Values > 5 should generally not be necessary

Temporarily decrease for test rendering if you don't need the additional bounces: for quicker rendering and a streamlined process

Final Gather Troubleshooting

Final Gathering Quality Filter

- Set to 1 if you have some very distinctive bright spots in your image
- Caused by reflections (and low accuracy)

Distinct spots caused by FG artefacts

Accuracy: 20 Point Density: 0.6 Point Interpolation: 10 *Render time: 0m47*

Accuracy: 40 Point Density: 0.6 Point Interpolation: 20 *Render time: 1m09*

Increased Accuracy (and Interpolation accordingly) for higher quality (less 'spotiness')

Accuracy: 40 Point Density: 1.0 Point Interpolation: 20 *Render time: 1m27*

Increased Point Density for a bit higher quality, but beacuse point interpolation and accuracy is still quite low, the effect is hardly noticeable: this scene clearly requires higher accuracy.

Accuracy: 40 Point Density: 0.8 Point Interpolation: 40 *Render time: 1m26*

Changing back the Point Density and just increasing the Interpolation quickly yields smoother results (albeit not too accurate)

Accuracy: 60 Point Density: 0.8 Point Interpolation: 40 *Render time: 1m48*

Increasing the Accuracy makes the render a bit better, but still not perfect.

Render Settings Presets

- You can create and load Presets
- Switch back and forth between test and production quickly
- Re-use settings that you commonly use: less fiddling, less mistakes

Preset Caveats

When you use Presets:

- Some settings can be set quite high
- Double-check your Ray Tracing, Sampling and FG Seetings after loading a preset
- Make adjustments and save the preset

The BK Renderfarm

- A stack of dedicated servers for rendering
- Available 24x7
- Total capacity:
 - Over 350 GHz of CPU power (in ~140 threads)
 - Over 320 Gigabyte of memory
 - ~17 tasks executed in parallel (20GHz, 18GB per task)

Using the Renderfarm

Workflow:

- Prepare your project and scene
- Configure your job
- Publish your scene
- Submit the job
- Wait...
- Get the results

Renderfarm Workflow

Using the Renderfarm

- Your Maya Project **must** be set properly otherwise your textures won't work
- Copying your entire project to the renderfarm file server may take a while:
 - use a wired network connection
 - Upload from the campus network
- Outside TU network: VPN is required » http://vpn.tudelft.nl

Using the Renderfarm

- The queue works on a first in first out basis
- But it can be managed otherwise to allow for a more fair allocation of resources
- If you your task to be incorrect, please remove it asap

BK Renderfarm

More information: renderfarm.bk.tudelft.nl. Note: The data on this page is not real-time. The data is at most 1 minute old.

Renderfarm Troubleshooting

If there's any problem with your job:

- Determine what's wrong: quality setting, textures, crash/error
- Use the Log file that's placed in the renderfam_logs folder within your folder on the renderfram file server

Each render produces a log file which is made available to you for inspection to troubleshoot any problems

Renderfarm Help

Documentation: http://wiki.bk.tudelft.nl/toi-pedia/Renderfarm

For any additional assistance, please refer to @Hok

Some Final Notes

- Make sure your polygons are detailed enough
- Check NURBs tessellation quality
- Texture resolution and filtering (esp. bump)
- Use lossless format (such as PNG, Tiff or TGA) instead of JPEG for textures, especially for bump and displacement
